Gene cluster involved in nogalamycin biosynthesis, and its use in production of hybrid antibiotics

Field of the invention

5

This invention relates to the gene cluster for nogalamycin biosynthesis derived from *Streptomyces nogalater*, and the use of the genes therein to obtain novel hybrid antibiotics for drug screening.

10 Background of the invention

Anthracyclines are antitumor antibiotics, mainly produced by *Streptomyces* sp. Daunomycin family of anthracyclines is commercially most important, since almost all of the around ten anthracyclines currently in clinical use, or in late clinical trials for cytotoxic drugs, belong to this family. Despite the long history of anthracyclines, three decades or so, the studies on their biosynthesis are still going on, and there is further interest to obtain novel molecules for the development of cancer chemotherapeutics. A method currently used for finding novel molecules for drug screening is genetic engineering. Cloning the genes for anthracycline biosynthesis facilitates the production of hybrid anthracyclines, as well as their use in combinatorial biosynthesis to generate novel molecules.

Nogalamycin, which was first described by Bhuyan and Dietz in 1965, is an anthracycline antibiotic produced by *Streptomyces nogalater*. It is highly active against tumor cells, whereas toxic properties of this compound have prevented its progress to clinical trials (Bhuyan and Smith, 1975). However, menogaril (7-O-methylnogarol) is a semisynthetic derivative of nogalamycin, and its value in the treatment of cancer has been studied (e.g. Yoshida *et al.*, 1996); the interest being now mainly in Japan. Structurally nogalamycin (Fig. 1) differs from most other anthracyclines, as e.g. from the daunomycin family, in two noteworthy features: (i) The stereochemistry at position nine is opposite, and (ii) it has a sugar moiety, in which nogalamine is attached at position 1 by a typical glycosidic bond, but it is also attached to carbon 2 by an extraordinary C-C bond. Structural elucidation of

nogalamycin was reported by Wiley *et al.* (1977). Furthermore, biosynthetic studies of nogalamycin have been published by Wiley *et al.* in 1978 giving information of the building blocks: The aglycone moiety is built from ten acetates; the neutral sugar, nogalose, is derived from glucose; and methyl groups of both of the sugars, nogalamine and nogalose, are transferred from methionine. The origin of nogalamine was not clearly solved by Wiley, but most probably nogalamine is also derived from glucose.

Molecular cloning of biosynthesis genes for anthracyclines has facilitated the studies on molecular genetics, providing tools for rational modifications of the structures, while also for surprising combinations with other antibiotics. Most of the interest has focused on daunomycin biosynthesis genes, as reported in several publications (Lomovskaya *et al.*, 1998; Rajgarhia and Strohl, 1997 and references therein). Some genes for aclacinomycin biosynthesis from *S. galilaeus* (Fujii and Ebizuka, 1997) and for rhodomycin biosynthesis from *S. purpurascens* (Niemi *et al.*, 1994) have been cloned as well. We have cloned the biosynthesis genes for nogalamycin, and successfully used the genes for producing hybrid anthracyclines. Most of the genes are involved in polyketide pathway, being responsible for the formation of a tricyclic intermediate, and they are reported in Ylihonko *et al.*, 1996a and b, and by Torkkell *et al.*, 1997. Despite the advances in molecular cloning, the biosynthetic pathway from glucose to sugars found in anthracyclines is still mainly hypothetical.

Regarding the genes for deoxyhexose pathway, Madduri *et al.* (1998) have reported that a gene derived from avermectin biosynthesis cluster caused the production of hybrid anthracyclines altering the sugar moiety when transferred into an *S. peucetius* mutant. The product obtained was epirubicin, a commercially important anthracycline. In this case a hydroxy group in the daunosamine moiety was in the opposite stereochemistry due to the action of an avermectin biosynthesis gene. *S. galilaeus* has been used as the host to prepare hybrid anthracyclines using the genes derived from rhodomycin pathway from *S. purpurascens* (Niemi *et al.*, 1994), and from nogalamycin biosynthesis cluster from *S. nogalater* (Ylihonko *et al.*, 1996a). The genes for nogalamycin pathway were used to generate the hybrid anthracycline production in *S.*

steffisburgensis producing typically steffimycin (Kunnari *et al.*, 1997). Previously, biosynthesis genes for actinorhodin have been expressed in *S. galilaeus* resulting in the formation of aloesaponarin (Strohl *et al.*, 1991). These hybrid compounds were modified in the aglycone moiety.

5

Summary of the invention

The present invention concerns a gene cluster of *Streptomyces nogalater*, most of the genes of which are derived from the deoxyhexose pathway for nogalamine and
 10 nogalose. Expressing a DNA fragment of the said region in *S. galilaeus*, which produces aclacinomycins, hybrid anthracyclines are obtained, in which the aglycone moiety is derived from *S. galilaeus*, whereas the sugar moiety is characteristic neither to *S. nogalater* nor to *S. galilaeus*. Furthermore, when inserting the gene included in said cluster, encoding a cyclase for nogalamycin, into a suitable plasmid construction,
 15 nogalamycinone is obtained, which is the aglycone of nogalamycin. Since the stereochemistry of nogalamycin differs from most other anthracyclines, using this gene enables the preparation of C-9 stereoisomers of the anthracycline molecules.

Detailed description of the invention

20

The experimental procedures of the present invention are methods conventional in the art. The techniques not described in detail here are given in the manuals by Hopwood
et al. "Genetic manipulation of Streptomyces: a laboratory manual" The John Innes
 Foundation, Norwich (1985) and by Sambrook *et al.* (1989) "Molecular cloning: a
 25 laboratory manual". The publications, patents and patent applications cited herein are given in the reference list in their entirety.

30

The present invention concerns particularly the gene cluster for nogalamycin biosynthesis (*Sno5*-cluster) causing the production of hybrid antibiotics with
 modifications in the sugar moiety. The invention concerns in specific the use of the
 genes for nogalamine/nogalose biosynthesis to generate hybrid antibiotics modified in
 sugar moieties. The invention also concerns the use of a specific cyclase gene

included in the gene cluster of the invention, to generate the C-9 stereoisomers of typical anthracyclines.

5 The gene cluster according to the present invention is linked to the earlier reported clusters for nogalamycin biosynthesis. The starting point of the present invention was the gene cluster for nogalamycin chromophor (International Patent Application WO 96/10581). ~~Subsequently, we have found some genes for the deoxyhexose pathway of~~
~~nogalamycin biosynthesis (Torkkell *et al.*, 1997), and a part of the fragment~~
~~comprising said genes was used to clone the genes for this invention.~~

10

The biosynthesis genes for nogalamycin can be isolated from *Streptomyces* sp., particularly from *S. nogalater*, which produces nogalamycin. Species which produce nogalamycin-like anthracyclines can also be used, e.g. *S. violaceochromogenes* producing arugomycin (Kawai *et al.*, 1987), or *S. avidinii* producing avidinorubicin
15 (Aoki *et al.*, 1991).

Genomic DNA of a *Streptomyces* strain carrying the genes for nogalamycin biosynthesis is used in preparing a genomic library. Suitable gene fragments for cloning may be obtained by any frequently digesting restriction enzyme. Typically
20 *Sau*3AI is used. The isolated fragments could be inserted by ligation in any *Escherichia coli* vector such as a plasmid, a phagemid, a phage, or a cosmid. A cosmid vector is preferred since it enables the cloning of large DNA fragments. A cosmid vector such as pFD666 (ATCC No. 77286) is suitable for this purpose, as it enables cloning of the fragments of about 40 kb. The *Bam*HI site of pFD666, giving
25 sticky ends to the *Sau*3AI fragments may be used for cloning. Commercially available kits may be used to pack the DNA in phage particles. Various *E. coli* strains can be used for the infection by the DNA packed. An appropriate *E. coli* strain is, e.g. XL1Blue MRF⁺, which is deficient in several restriction systems.

30 Using *E. coli* as a host strain for the genomic library, hybridization is an advantageous screening strategy. The probe for hybridization may be any known fragment derived from the nogalamycin gene cluster, but a short fragment of about 1

kb derived from one end of the biosynthetic region previously cloned is preferred. Colonies for the genomic library are transferred for filter hybridization to membranes, preferably to nylon membranes. Since the average size for a genomic DNA fragment is 40 kb, 2300 colonies gave 99,99% probability to find the expanded region for nogalamycin biosynthesis. Any method for hybridization may be used but, in particular, the DIG System (Boehringer Mannheim, GmbH, Germany) is useful. Since the probe is homologous to the hybridized DNA, it is preferable to carry out the stringent washes of hybridization at 70°C in a low salt concentration according to Boehringer Mannheim's manual "DIG System User's Guide for Filter Hybridiza-
 10 tion". At least 80% homology is suggested to be needed for a DNA fragment to bind a probe in the conditions used for washes.

Using this protocol, seven clones out of about 5000 gave positive signals, and were picked up for DNA isolation. Restriction mapping is an appropriate technique for
 15 characterizing the clones. The positive clones may be digested with convenient restriction enzymes to demonstrate the physical linkage map of the DNA fragments. The cosmid used for cloning was a shuttle cosmid replicating in both *E. coli* and *Streptomyces* sp. However, the transfer of the recombinant cosmids in *S. lividans* TK24, which is a typically used laboratory strain in cloning *Streptomyces*, resulted in
 20 deletions, and was omitted. Instead, we rather used in the expression studies the plasmid pIJ486, a high copy number *Streptomyces* plasmid. However, any plasmid being able to stably replicate in *Streptomyces* may be used for this purpose.

Two *Bgl*II fragments of one of the clones were separately inserted into pIJ486
 25 vectors, and the two plasmids obtained were transferred into a primary host, *S. lividans* TK24. The recombinant plasmids obtained (pSY42 and pSY43), containing a 10 kb and a 7 kb fragment from *S. nogalater* genomic DNA, respectively; were isolated from the primary host and further introduced into other *Streptomyces* strains by protoplast transformation. The recombinant plasmid containing the 10 kb fragment
 30 caused the production of hybrid anthracyclines in the *S. galilaeus* mutant strain H039, which endogenously produces aklavinone-rhodinose-rhodinose-rhodinose. A few other *S. galilaeus* strains (H075, H026, H063) mutated in deoxyhexose pathway

for sugars in aclacinomycin were used in transformation, and new hybrid compounds were obtained. Since the structure of nogalamycin is almost unique among anthracyclines, the plasmids could be transferred to other anthracycline-producing strains, such as *S. peucetius*, which produces daunomycin, and *S. purpurascens*, which produces rhodomycins, to modify the structures of the characteristic antibiotics.

As the cloned cluster was linked to nogalamycin biosynthesis region already known, its ability to generate the modification in sugar moiety suggested the presence of the genes for deoxyhexose pathway. However, sequencing is necessary to deduce the function of the genes in the cluster cloned. The DNA fragments of 10 kb and 7 kb were further inserted into the plasmid pSL1190 for subcloning. Sequencing strategies such as a deletion set of the DNA fragments, shotgun cloning or primer walking could be used, but we prefer to use restriction fragments for subcloning. Using ABI PRISM system (Perkin-Elmer) for sequencing it is possible to get 500 to 700 bases per one reaction, which means that about 1 kb fragments sharing overlapping bases are needed for sequencing. For this purpose, 27 subclones were constructed.

Sequencing of the flanked *Bgl*II fragments consisting of about 16000 bp revealed 15 complete ORFs. The sequence analysis can be made by any computer based program, such as GCG (Madison, Wisconsin, USA) package. According to the present invention the putative gene functions as deduced from the sequence homology of those available in the libraries are

- aminotransferase (*snogI*), not completed
- 1. dTDP-glucose synthase (*snogJ*)
- 2. aminomethyl transferase (*snogA*)
- 3. polyketide cyclase, (*snoaM*)
- 4. a gene of deoxyhexose pathway, unknown (*snogN*)
- 5. hydroxylase, (*snoaG*)
- 6. dTDP-4-dehydrorhamnose reductase (*snogC*)
- 7. dTDP-glucose 4,6-dehydratase (*snogK*)
- 8. NAME cyclase (*snoaL*)

9. unknown (*snoK*)
 10. glycosyl transferase, GTF (*snogD*)
 11. unknown (*snoW*)
 12. glycosyl transferase, GTF (*snogE*)
 - 5 13. unknown (*snoL*)
 14. unknown (*snoO*)
 15. C-7 ketoreductase (*snoaF*)
-
- unknown (*snoN*), not completed
-

- 10 Gene designations: g means that the gene involved in biosynthesis of the glycosidic proportion including glycosyl transferases, whereas a points out that the gene is needed for the formation of the aglycone moiety.

- 15 Considering the proposed biosynthetic pathway for nogalamycin shown in Fig 3. we are able to cause several changes for the structures of antibiotics by the genes identified, including *snoaL*, responsible for the cyclization of the fourth ring of the aglycone moiety while determining the stereochemistry of the anthracyclinone, and the genes affecting the formation of nogalamine and nogalose (*snogJ*, *snogK*, *snogN*, *snogC*, *snogA*), and, in addition, the genes responsible for joining the sugar residues to the aglycone moiety (*snogD* and *snogE*).

- 20 These genes could be separately inserted in a vector using suitable restriction sites, or by amplifying the genes by PCR. The fragments may contain an intrinsic promoter, or a promoter may be separately cloned. It is advantageous to use a vector carrying a
- 25 promoter to allow expression of the genes in a *Streptomyces* strain. The plasmid pIJE486 contains a promoter *ermE* for erythromycin resistance gene, allowing constitutive expression of the genes inserted in a correct orientation. Special attention is drawn to the gene encoding a cyclase for the aliphatic ring, but any gene of said cluster may be expressed in *Streptomyces* hosts. The said cyclase converts the
- 30 stereochemistry at C9 of auramycinone in TK24, if inserted into the plasmid possessing the other genes for auramycinone biosynthesis, except the cyclase responsible for the typical stereochemistry of anthracyclines.

Streptomyces strains, in particular *S. galilaeus*, carrying the recombinant plasmids are cultivated in media wherein antibiotics are produced. The hybrid compounds are extracted with organic solvents from the culture broth, and the compounds are separated and purified using chromatographic techniques.

5

According to this invention *S. galilaeus* H039 carrying the plasmid pSY42 and designated as H039/pSY42 produces aklavinone-4'-epi-2-deoxyfucose in E1 medium supplemented with thiostrepton to give selection pressure for the plasmid containing strains.

10

S. lividans TK24 carrying the plasmid pSY15c containing the genes for the nogalamycin chromophore and the genes for a cyclase (*snoaL*) and a ketoreductase (*snoaF*), was cultivated in E1 medium supplemented with thiostrepton. The compound 9-epi-auramycinone was produced, and this structure is now called nogalamycinone. Any DNA fragment of the invention subcloned from a 17 kb nogalamycin biosynthesis region can be inserted in a vector replicating in *Streptomyces*, and the products may be produced by fermentation of the plasmid containing strains.

20

Brief description of the drawings

Fig. 1 shows the structures of nogalamycin, daunomycin and aclacinomycin.

25

Fig. 2 is a diagram of the gene cluster (*Sno5*) of the invention for nogalamycin biosynthesis.

Fig. 3 describes the proposed biosynthesis pathway for nogalamycin.

30

Fig. 4 shows a diagram of the plasmid pSY15c. The genes *snoaL* (aL) and *snoaF* (aF) shown black are inserted in the plasmid pSY15 to give pSY15c. aL represents a cyclase *snoaL* and aF is for C-7 ketoreductase *snoaF*. pSY15 (WO 96/10581) generates the production of a tricyclic intermediate for

nogalamycin biosynthesis in *S. lividans*. The abbreviations **a1**, **a2** and **a3** refer to the genes *snoa1*, *snoa2* and *snoa3*, respectively, for minimal PKS. **rA** is the *snoA* gene for an activator, **aB** is the *snoaB* gene for oxygenase, **aC** is the *snoaC* gene for methylase, **aD** is the *snoaD* gene for polyketide ketoreductase and **aE** is the *snoaE* for aromatase. **gF** (the *snogF* gene) and **gG** (the *snogG* gene) involved in the deoxyhexose pathway are not functional in the construct. ~~**aph** is an aminoglycoside phosphotransferase gene,~~ and **tsr** is a thiostreptone resistance gene.

10 Examples to further illustrate the invention are given hereafter.

EXPERIMENTAL

Materials used

15 Restriction enzymes used were purchased from Promega (Madison, Wisconsin, USA) or Boehringer Mannheim (Germany), and alkaline phosphatase from Boehringer Mannheim, and used according to the manufacturers' instructions. Proteinase K was purchased from Promega and lysozyme from Sigma (St. Louis, USA). HybondTM-N nylon membranes used in hybridization were purchased from Amersham
20 (Buckinghamshire, England), DIG DNA Labelling Kit and DIG Luminescent Detection Kit from Boehringer Mannheim. Qiaquick Gel Extraction Kit from Qiagen (Hilden, Germany) was used for isolating DNA from agarose.

Bacterial strains and their use

25 *Escherichia coli* XL1 Blue MRF' was used for cloning.
Streptomyces nogalater ATCC 27451; the gene cluster of nogalamycin biosynthesis was cloned from this strain.
The host strains to express the genes cloned were:
Streptomyces lividans TK24, also used as a primary host to clone DNA propagated in
30 *E. coli*.
Streptomyces galilaeus H039, produces aklavinone-rhodinose-rhodinose-rhodinose

Streptomyces galilaeus H026, produces aclacinomycin N, ACMN, (aklavinone-rhodosamine-2-deoxyfucose-rhodinose)

Streptomyces galilaeus H063, produces aklavinone

Streptomyces galilaeus H075, produces aklavinone-rhodosamine-2-deoxyfucose-2-deoxyfucose

The detailed description of the mutants H039 and H026 is given in Ylihonko *et al.* (1994) and of H075 in the FI patent application No. 981062 (Ylihonko *et al.*, 1998). H063 has not been described in the literature but it was obtained by NTG

mutagenesis of *S. galilaeus*, and selected to be used as the host strain in the hybrid compound production, as it accumulates aklavinone without any sugar residues.

Plasmids

E. coli - *Streptomyces* shuttle cosmid pFD666 (ATCC 77286) was used for cloning the chromosomal DNA. *E. coli* cloning vectors pSL1190 (Pharmacia) and pUC19 were used for preparing the subclones.

pIJ486 is a high copy plasmid vector provided by prof. Sir David Hopwood, John Innes Centre, UK (Ward *et al.*, 1986)

pIJE486 is a vector containing *ermE* gene in the polylinker of pIJ486 (Bibb *et al.*, 1985).

pSY15 is a pIJ486 based plasmid construct, wherein the genes of polyketide pathway for nogalamycin biosynthesis were cloned (Ylihonko *et al.*, 1996a).

Nutrient media and solutions

For cultivation of *S. nogalater* for total DNA isolation TSB medium was used.

Lysozyme solution (0.3 M sucrose, 25 mM Tris, pH 8 and 25 mM EDTA pH 8) was used in isolation of total DNA. TE buffer (10 mM Tris, pH 8.0 and 1mM EDTA) was used to dissolve the DNA.

TRYPTONE-SOYA BROTH (TSB)

Per litre: Oxoid Tryptone Soya Broth powder 30 g.

ISP4

5 Bacto-ISP-medium 4, Difco; 37 g/l.

E1 Per litre in tap water:

	glucose	20 g
	soluble starch	20 g
10	Farmamedia	5 g
	yeast extract	2.5 g
	K ₂ HPO ₄ •3H ₂ O	1.3 g
	MgSO ₄ •7H ₂ O	1 g
	NaCl	3 g
15	CaCO ₃	3 g

pH adjusted to 7.4 before autoclaving

20 General methods

NMR data was collected with a JEOL JNM-GX 400 spectrometer at the ambient temperature. ¹H and ¹³C NMR samples were internally referenced to TMS.

25 The anthracycline metabolites were detected by HPLC (LaChrom, Merck Hitachi, pump L-7100, detector L-7400 and integrator D-7500) using a LiChroCART RP-18 column (4.6x250mm). Acetonitrile:potassium hydrogen phosphate buffer (60 mM, pH 3.0 adjusted with citric acid) was used as the mobile phase. Gradient system starting from 65% to 30% of potassium dihydrogen phosphate buffer was used to separate the compounds. The flow rate was 1 ml/min and the detection was effected at 430

30 nm.

ISP4 plates supplemented with thiostrepton (50 µg/ml) were used to maintain the plasmid carrying cultures.

Example 1. Cloning the gene cluster for nogalamycin biosynthesis

1.1 Cosmid library

For the isolation of total DNA, *Streptomyces nogalater* (ATCC 27451) was grown
 5 for three days in 50 ml of TSB medium supplemented with 0.5% of glycine. The
 cells were harvested by centrifuging for 15 min at 3900 x g in 12 ml Falcon tubes,
 and the cells were stored at -20°C. Cells from a 12 ml sample of the culture were
 used to isolate the DNA. 5 ml of lysozyme solution containing 5 mg of lysozyme/ml
 was added onto the cells, incubated for 20 min at 37°C. 500 µl of 10% SDS
 10 containing 0.7 mg of proteinase K was added onto the cells and incubated for 80 min
 at 62°C, another 500 µl of 10% SDS containing 0.7 mg of proteinase K was added,
 and incubation was continued for 60 min. The sample was chilled on ice and 600 µl
 of 3M NaAc, pH 5.8 were added, and the mixture was extracted with equilibrated
 phenol (Sigma). The phases were separated by centrifuging at 1400 x g for 10 min.
 15 The DNA was precipitated from the water-phase with equal volume of isopropanol to
 spool with a glass rod, and washed by dipping to 70% ethanol, air dried and
 dissolved in 500 µl of TE-buffer.

The chromosomal DNA was partially digested with *Sau3AI*. The DNA fragments
 20 were separated by agarose gel electrophoresis, and the fragments of 30 to 50 kb were
 cut from the 0.3% low gelling temperature SeaPlaque® agarose. The DNA bands
 were isolated from the gel by heating to 65°C, extracting with equal volume of
 equilibrated phenol, and the phases were separated by centrifuging for 15 min at
 2500 x g. The phenol phase was extracted with TE buffer, centrifuged and the water
 25 phases were pooled. The DNA was precipitated by adding 0.1 volumes of NaAc, pH
 5.8 and 2 volumes of ethanol at -20°C for 30 min, centrifuged for 30 min at 15 000
 rpm in Sorvall RC5C centrifuge using SS-34 rotor with adapters for 10 ml tubes.
 The pellet was air dried and dissolved in 20 µl of TE buffer. The isolated fragments
 were ligated to pFD666 cosmid vector digested with *Bam*HI and dephosphorylated.
 30 The DNA was packed to phage particles, and infected to *E. coli* using Gigapack® III
 XL Packing Extract Kit according to the manufacturer's instructions.

1.2 Identification of the clones by hybridization

- The infected cells were grown on LB plates containing 50 $\mu\text{g/ml}$ kanamycin and transferred to HybondTM-N nylon membranes (Amersham). The membranes were handled according to the protocol described in Boehringer Mannheim's manual "The DIG System User's Guide for Filter Hybridization". The probe used to screen the colonies for an expanded nogalamycin gene cluster was a 1.07 kb *SacI* fragment from the cluster described earlier (Torkkell *et al.*, 1997). The plasmid carrying the probe was digested with *SacI*, and the fragment was separated from the vector by agarose gel electrophoresis and isolated from the gel using Qiaquick Gel Extraction Kit (Qiagen). The probe was labelled by digoxigenin using random prime labelling system according to Boehringer Mannheim's manual "The DIG System User's Guide for Filter Hybridization". 5000 colonies were screened by hybridization at 70°C using the probe described. Positive colonies were detected using DIG Luminescent Detection Kit (Boehringer Mannheim). Seven colonies gave a positive signal.
- Cosmids from the positive clones were isolated from a 5ml culture by alkaline lysis method. Restriction analysis showed that the cloned fragments overlapped each other representing at least 60 kb of the continuous DNA. The positive clones obtained were designated as pFDSno1 to pFDSno7.

1.3. Subcloning the fragments for sequencing

- Clone No. 5, designated as pFDSno5, was digested with *Bgl*II, and for subcloning two fragments of about 10 kb and 7 kb were isolated and ligated to pSL1190 digested with *Bgl*II and dephosphorylated. The plasmids obtained were named as pSn42 and pSn43, respectively. These two fragments cover the DNA region flanked to the previously characterized area of nogalamycin biosynthesis cluster. To determine the nucleotide sequence of the whole 17 kb region cloned in pSn42 and pSn43 the convenient restriction sites were used to subclone the fragments to the vector pUC19 or pSL1190 giving 16 subclones from the insert of pSn42 and 11 subclones of pSn43.
- E. coli* XL1 Blue MRF' cells were cultivated overnight at 37 °C in 5 ml of LB-medium supplemented with 50 $\mu\text{g/ml}$ of ampicillin. To isolate plasmids for

sequencing reactions Wizard Plus Minipreps DNA Purification System kit of Promega, or Biometra silica spin plasmid miniprep kit of Biomedizinische Analytik GmbH were used according to the manufacturers' instructions.

- 5 DNA sequencing was performed using the automatic ABI DNA sequenator (Perkin-Elmer) according to the manufacturer's instructions.

1.4 Sequence analysis and the deduced functions of the genes

~~Sequence analyses were effected using the GCG sequence analysis software package~~

- 10 (Version 8; Genetics Computer Group, Madison, Wisconsin, USA). The translation table was modified to accept also GTG as a start codon. Codon usage was analysed using published data (Wright and Bibb 1992).

- 15 According to the CODONPREFERENCE program the sequenced DNA fragment contained 15 complete open reading frames (ORFs), and the 5' end of other two ORFs in the both ends of the fragment according to the invention. The functions of the genes were concluded by comparing the amino acid sequences translated from their base sequences to the known protein sequences in the data banks. The results are shown in Table 1. The positions given refer to the appended sequence listing.
- 20 The amino acid sequences of the peptides are given in SEQ ID NO:2 to SEQ ID NO:18.

*, nucleotide sequence of about 100 bp, not known

1.5 Expression cloning

The 10 kb *Bgl*III fragment from pFDSno5 was cloned into the plasmid pIJ486 and the plasmid obtained was named as pSY42. Correspondingly, the 7 kb *Bgl*III fragment from pFDSno5 was cloned into the plasmid pIJE486, and the plasmid pSY43 was obtained. Plasmid pSY42 was introduced into *S. lividans* strain TK24 by protoplast transformation, isolated from it and further introduced into *S. galilaeus* mutant H039, and after propagation in H039, transferred to other *S. galilaeus* mutants blocked in the deoxyhexose pathway for characteristic sugars of aclacinomycins (H075, H026, and H063). E1 medium was used for anthracycline production, and the products were extracted from the culture with toluene:methanol (1:1) at pH 7. Anthracycline metabolites were analyzed by HPLC. The products of the mutants H039, H026, H063 and H075 carrying pSY42 differed from those obtained by the mutants without the plasmid.

According to the sequence analysis pSY42 contained a cyclase designated as NAMEC (nogalonic acid methyl ester cyclase), and in pSY43 a ketoreductase gene was identified. Expression constructions were prepared which contained all the genes needed for the formation of nogalamycin aglycone. A 1.4 kb *Bam*HI-*Sac*I fragment from pSY42 (containing NAMEC) and a 1.1 kb *Mlu*I-*Kpn*I fragment from pSY43 carrying the gene for a ketoreductase of C-7 keto group were ligated to pSY15 linearized by *Sac*I, to form the plasmid pSY15c (Fig. 4). Plasmid pSY15c was introduced into *S. lividans* TK24, and the strain TK24/pSY15c was cultivated in E1 medium supplemented with thiostrepton. An aglycone compound was produced, and this structure is now called nogalamycinone.

Example 2. Compounds generated by the *sno5*-cluster

2.1 Production and purification of the products derived from H039/pSY42 and TK24/pSY15c

The seed culture, 180 ml of E1 culture of the plasmid containing strain, H039/pSY42 or TK24/pSY15c, was obtained by cultivating the strain in three 250 ml Erlenmeyer flasks containing 60 ml of E1 medium supplemented with thiostrepton (5 µg/ml) for

four days at 30°C, 330 rpm. The combined culture broths (180 ml) were used to inoculate 13 l of E1 medium in a fermentor (Biostat E). Fermentation was carried out for seven days at 28°C (330 rpm, aeration: 450 l/min).

- 5 The cells were harvested by centrifuging. 2.6 l of methanol was used to break the bacterial cells and to extract anthracycline metabolites accumulated. The anthracycline metabolites were extracted using 2 l of dichloromethane at pH 6. The organic layer was evaporated to dryness. The viscous residue was flashed through a polyamide (11) column using water:methanol from 1:9 to 0:10 as the eluent. Pooled
- 10 fractions containing the compounds were further purified on a Merck-Hitachi HPLC using preparative reversed phase column (LichroCART RP-18, 5 μ m) with mobile phase acetonitrile:1 % AcOH in water (1:1). Evaporation of acetonitrile gave pure products as yellow powders dried under vacuum.

15 2.2 Structural elucidation of the compounds derived from H039/pSY42 and from TK24/pSY15c

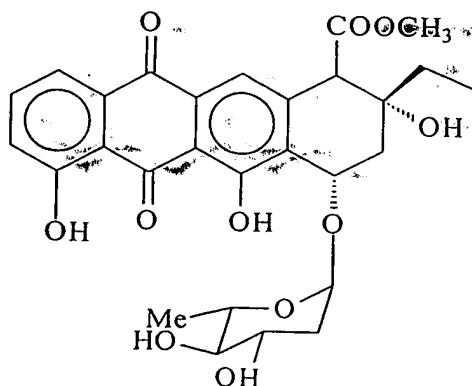

NMR analysis, included ¹H NMR, ¹³C NMR, NOE, DEPT and HMBG techniques. Protons were assigned using NOESY and 2D pTOCSY techniques and carbons using DEPT and HMBG techniques.

20

As deduced from the data given in Tables 2 and 3, the structures revealed were aklavinone-4'-epi-2-deoxyfucose from the culture of H039/pSY42, and 9-epi-auramycinone (=nogalamycinone) from the culture of TK24/pSY15c. The chemical structures of the compounds are shown below in Formula I and Formula II,

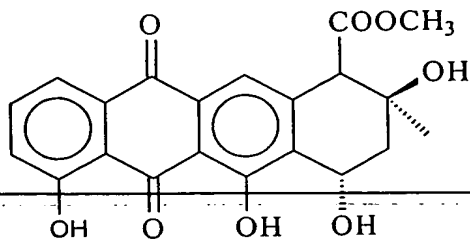

25 respectively.

Claims

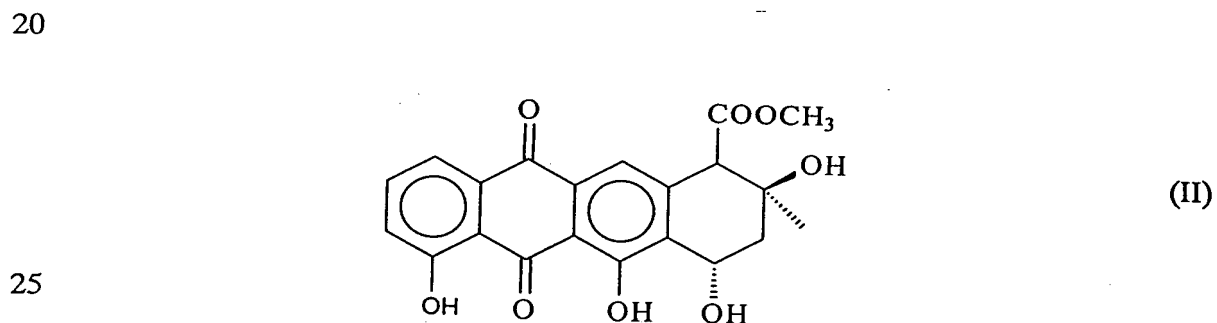

1. Isolated and purified DNA fragment, which is the gene cluster for the anthracycline biosynthetic pathway of the bacterium *Streptomyces nogalater*, being included in a 10kb and a 7kb flanked *Bgl*II fragments of *S. nogalater* genome.
2. ~~The DNA fragment according to claim 1, comprising the nucleotide sequence given in SEQ ID NO:1, or a sequence showing at least 80% homology to said sequence.~~
3. A recombinant DNA, which comprises the DNA fragment according to claim 1 or 2, cloned in a plasmid replicating in *Streptomyces*.
4. The recombinant DNA according to claim 3, which is the plasmid pSY15c, comprising a 1.4 kb *Bam*HI-*Sac*I fragment from the plasmid pSY42 and a 1.1 kb *Mlu*I-*Kpn*I fragment from the plasmid pSY43.
5. Plasmid pSY42, deposited in *S. lividans* strain TK24/pSY42 with the deposition number DSM 12451.
6. Plasmid pSY43, deposited in *S. lividans* strain TK24/pSY43 with the deposition number DSM 12452.
7. A process for the production of hybrid compounds, comprising transferring the DNA fragment according to claim 1 or 2 into a *Streptomyces* host, cultivating the recombinant strain obtained, and isolating the compounds produced.
8. The process according to claim 7, wherein the *Streptomyces* host is a *Streptomyces galilaeus* host.

9. The process according to claim 8, wherein the *Streptomyces galilaeus* host is selected from the strains H026, H039, H063 and H075, which are mutant strains of *S. galilaeus* ATCC 31615.

10. The process according to claim 8, wherein an anthracycline is produced, which has the following formula I

11. The process according to claim 8, wherein an anthracyclinone is produced, which has the following formula II

30 12. A process for the production of hybrid compounds, comprising transferring at least one of the genes selected from the group consisting of *snogJ*, *snogA*, *snoaM*, *snogN*, *snoaG*, *snogC*, *snogK*, *snoaL*, *snoK*, *snogD*, *snoW*, *snogE*, *snoL*, *snoO* and

snoaF into a *Streptomyces* host, said genes being derived from the DNA fragment of claim 1 or 2, cultivating the recombinant strain obtained, and isolating the compounds produced.

- 5 13. The process according to claim 12, wherein the gene *snoaL* encoding NAME cyclase is transferred into a *Streptomyces* host.

14. The process according to claim 12, wherein at least one of the genes *snogD* and *snogE* encoding glycosyl transferases is transferred into a *Streptomyces* host.

10

15. The process according to claim 12, wherein at least one of the genes *snogJ*, *snogN*, *snogC*, *snogK* and *snogA* affecting the formation of nogalamine and nogalose is transferred into a *Streptomyces* host.
